Discrete Probabilities (having its own importance)

[Discrete vs Continuous
any value
within a range
sports ~~team~~ band]

Probability is a science of predicting the
likelihood of occurrences.

Generally, between 0 and 1.

✓ Event ✓ Number of outcomes

✓ Sample space : set of all possible outcomes
i.e. Ω

$$P(A) = \frac{n(A)}{n(S)}$$

Probability

What background/prerequisite we need
to ~~master~~ before being
able to do probability?

To my knowledge,

— permutations and combinations

In other words,

~~An~~ ^{the} applications of permutation and combination
can be finding probability.

To be able to compute number of ways/
outcome of an experiment.

∴

Independent Events

In the occurrence or non-occurrence of the event A does not affect the occurrence or non-occurrence of the event B then two events A and B are said to be independent events.

[p.s. Note that the word ~~dependable~~ has a meaning of reliable, can count on)

i.e. 3 students appeared in an exam

passing of student 1 is independent of passing of student 2.

i.e. Drawing of two cards ~~one after another~~ from a pack of cards
[With replacement given]

Complementary event

Let A be an event of a given sample space S .
~~The event A~~ is said to be a complementary event if A^c consists of all the sample points of S which are not in A .

$$A \cap A^c = \phi$$

$$A \cup A^c = S$$

~~elementary~~ elementary set-theoretic
concepts enable us to
introduce new definitions
precisely and concisely.

$$A \cap B$$

event that both
A and B occurs.

If A and B have no sample points common

$$A \cap B = \phi, \text{ empty set}$$

this leads to

Mutually Exclusive or disjoint events
bcz, occurrence of A excludes

that of B and vice versa.

i.e. tossing of a die turns up

↳ even number that is 1, 3, 5

↳ odd number

2, 4, 6

$A \cup B$, ~~Both~~ A or B or both events occur together.

Corresponding to samples of $A \cup B$.

$A - B$, The event A occurs but B does
~~not~~ correspond to set of
samples $A - B$.

$A \oplus B$, event that ^{one} A or B but not both
occurring correspond to set of
samples $A \oplus B$

Collectively Exhaustive events

Two or more events that are said to be collectively exhaustive if ~~they~~ at least one of the events must occur.

In other words,
their union must cover all the sample space within entire

Rolling a dice

Ⓐ getting even Ⓑ getting odd

Imp: None is not an option.

Because, $\{1, 3, 5\} \cup \{2, 4, 6\} = \{1, 2, 3, 4, 5, 6\}$

Odds in favor

$$\frac{p}{1-p}$$

odds in against

$$\frac{1-p}{p}$$

Discrete Sample Space

Sample space S that has a finite number
or countably infinite number of samples.
(sample points)

For now, we are not talking completely
infinite sample space case.

Experimental model

- Assumption
All events to be mutually exclusive
and collectively exhaustive.

~~head, tail~~ ~~[standing on its side]~~ not a valid coin

- only one at a time

~~can't~~ be 'None' of them.

Event

is a subset of ~~the outcomes~~

SIMPLE event

contains only one sample point.

Compound event

contains more than one sample points.

A different perspective

Can we think of probability of -ve or larger than 1 value?

If the probability associated with a sample is a measure of frequency of occurrence of the ~~outcome~~ of an experiment then ~~-ve~~ not possible.
Probability

Can we think sum of all probabilities other than 1?

work it out yourself!

for Time being let's
ASSUME

the probabilities of the outcomes of an
experiment are given to us by

either
— based on statistical data

(experiments)

i.e. ~~fair~~ coin vs special coin
(regular)

(like, sholey
movie
Amitabh had)

regular die vs crooked die

(like mama shakuni
had in
Mahabharata)

- simply on one's intuitive
guesstimation
(smart estimation)

In that case,

~~probability is still counted~~

same way but ~~values considered~~ are
different.

i.e. For a (ROOKED) die

given that
probability of getting 1 $\rightarrow \frac{1}{3}$
remaining 2, 3, 4, 5, 6 $\rightarrow \frac{2}{3}$

~~We know~~
maters

$$\frac{1}{3} + 5\left(\frac{2}{15}\right) \Rightarrow \frac{1}{3} + \frac{2}{3} = \frac{3}{3} = 1 \quad \text{still feels good.}$$

But the probability
~~of getting odd~~ numbers

1, 3, 5

$$\begin{aligned} & \frac{1}{3} + \frac{2}{15} + \frac{2}{15} \\ &= \frac{5}{15} + \frac{2}{15} + \frac{2}{15} \\ &= \frac{9}{15} \\ &= \frac{3}{5} = 0.60 \end{aligned}$$

Getting even

$$\frac{2}{5} = 0.40$$

in a regular die
this is odd

$$\begin{aligned} \frac{1}{6} + \frac{1}{6} + \frac{1}{6} &= \frac{3}{6} \\ &= \frac{1}{2} \\ &0.50 \end{aligned}$$

$$\left. \begin{array}{l} \text{even} \\ 2, 4, 6 \\ \frac{1}{6} + \frac{1}{6} + \frac{1}{6} \end{array} \right\} 0.50$$

Example

Rolling 2 dice

What is the probability of
getting sum as 9?

Number of total samples =

which are they?

How will we use number of samples to
~~get answer sum 9?~~

two dice
each can have

1, 2, 3, 4, 5, 6 \Rightarrow 6 count

Value of product

$$6 \times 6 = 36$$

The sample space $S(U)$

36 outcomes
possible.

$$n(S) = 36$$

$\underset{\text{min}}{1}, \underset{\text{max}}{2}, \underset{\text{min}}{3}, \underset{\text{max}}{4}, \underset{\text{min}}{5}, \underset{\text{max}}{6} \times \underset{\text{min}}{1}, \underset{\text{max}}{2}, \underset{\text{min}}{3}, \underset{\text{max}}{4}, \underset{\text{min}}{5}, \underset{\text{max}}{6}$

Can we use generating function,
~~polynomial~~ binomial, finding co-efficient
of a term smartfully any such concept?

Yes \Downarrow

$$(x + x^2 + x^3 + x^4 + x^5 + x^6) \times (x + x^2 + x^3 + x^4 + x^5 + x^6)$$

$$(x + x^2 + x^3 + x^4 + x^5 + x^6)^2$$

$$\left(\underbrace{1 + x + x^2 + x^3 + x^4 + x^5 + x^6}_{a=1} - 1 \right)^2$$

$$a = 1$$

$$r = x$$

$$n = 7$$

$$\left(\frac{1 \cdot (1 - x^7)}{1 - x} - 1 \right)^2$$

$$= \left(\frac{1 - x^7 - 1 + x}{1 - x} \right)^2 =$$

$$\frac{x^2 (1 - x^6)^2}{(1 - x)^2}$$

~~Binomial Theorem~~

$$(1+x)^{-n} = \sum_{r=0}^{\infty} (-1)^r \binom{n+r-1}{r} x^r$$

$$(1+x)^{-2} = \sum_{r=1}^{\infty} r x^{r-1}$$

$$= 1 + 2x + 3x^2 + 4x^3 + \dots$$

Ex count i $x^2 (1-x^6)^2 (1-x)^{-2}$

$$x^2 (1-2x^6+x^{12}) (1+\boxed{2x}+3x^2+4x^3+\dots)$$

$$= (x^2 - 2x^8 + x^{14}) (1 + \boxed{2x} + 3x^2 + 4x^3 + \dots)$$

(2+7)

$$8x^9 - 4x^9$$

$$= 4$$

$\begin{matrix} 3,6 \\ 4,5 \\ 5,4 \\ 6,3 \end{matrix}$
 $\left. \begin{matrix} \uparrow \\ \left. \begin{matrix} \text{pairs} \\ \text{having} \\ 9 \\ \text{sum.} \end{matrix} \right\} \end{matrix} \right\} 4$

hence,

$$P(A)_{\text{probability}} = \frac{n(A)}{n(S)}$$

$$= \frac{4}{36}$$

$$= \frac{1}{9}$$

~~probability that rolling two dice~~

end up summing to 9 result.
of faces

G

There is observation

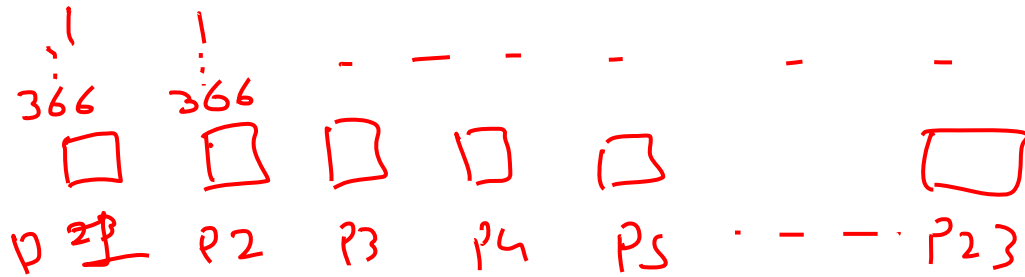

" Out of 23 people the chance
is less than 50-50 that
no 2 of them will have
the same birthday "

- Assumptions?

→ ~~Sample space~~

→ What is 23?

let's accept 366 days of year (julian)

order is
of importance

Sample space 366^{23}

repetition
allowed

very similar to

putting decimal (0-9)

into 4 digit space (length)
number.

10^4

on other hand

putting binary (0-1)

into 4 digit space (length)

2^4

Out of 365^{23} samples,

we need to find sample count
where given the sequence, all days from
 p_1 to p_{23} are different
that is they have different birthday
meaning no two or more have same.

How many ways can we arrange
days from 1-366 into 23

without repetition and order is of
importance?

$$Perm(366, 23)$$

Hence,

$$Probability \text{ is } \frac{Perm(366, 23)}{366^{23}}$$

$$= 0.694$$

$$< 50\%$$

The observation is
confirmed by maths of ~~probability~~

Example

8 students are standing in line
for interview.

Determine probability that there are
exactly 2 freshman [year 1]
2 sophomores [year 2]
2 juniors [year 3]
2 seniors [year 4]
in the line.

- Sample Space

- Use of perm/combination
variations?

Equiprobable samples!

Sample space

~~$\frac{8!}{2!}$ samples~~

4 types of student
8 student count.

Two students from each class
~~number of ways~~

$$\frac{8!}{2! \cdot 2! \cdot 2! \cdot 2!}$$

Probability of event

$$= \frac{\frac{8!}{2! 2! 2! 2!}}{48}$$

count of event

Sample space

$$= 0.0385$$
